Python Data Structures Cheat Sheet

. .

List			
Package/Method	Decription	Code Example	
		Symtax: list_name.append(element)	
append()	The 'append()' method is used to add an element to the end of a fact.	Example:	
		<pre>fruits = ['apple", 'banama", 'orange"] fruits.append('mange") print(fruits)</pre>	
	Example 1:		
copy()	The 'coppt') method is used to create a shallow copy of a list.	<pre>my.list = {2, 2, 3, 4, 5} com_list = 92, list.copy() print(now_list) * copyit (1, 2, 2, 4, 3)</pre>	
count()	The 'county' method is used to count the number of occurrences of a specific element in a list in Python.	Example: my list = [1, 2, 2, 3, 4, 2, 5, 2]	
count)	Inc. county) memode is succed to count the number of necurrences of a specuric connect in as not in Python.	<pre>my_list = [2, 2, 2, 3, 4, 2, 5, 2] count = sp_list.count(2) print(count) 4 Cloput 4 </pre>	
	A list is a bill-in data type that represents an ordered and mutable collection of elements. Lists are enclosed in square brackets [] and elements are separated by commas.	Example:	
Creating a list	A list in a built-in data type that represents an ordered and mutable collection of climents. Lists are exclosed in square brackets [1] and climents are separated by commas.	fruits = ("apple", "banana", "orange", "mango")	
del		Example:	
del	The 'del' statement is used to remove an element from list. 'del' statement removes the element at the specified index.	my_list = 720, 20, 30, 44, 50] all my_list[] # Semones the element at index 2 print(my_list) # Cotput: [30, 20, 40, 50]	
		Syntax:	
		list_name.extend(iterable)	
extend()	The 'extendy' method is used to add multiple elements to a list. It takes an iterable (such as another list, tuple, or arring) and appends each element of the iterable to the original list.	Example: fruits = ["apple", "banna", "orange"]	
		fruits = ["spaje", "hamen", "hamen"] sure-fruits = ["hamen", "hamen"] fruits.astani(sure, "ruits) print(fruits)	
		Example:	
Indexing	Indicating in a list allows you to access individual elements by their position. In Python, indexing stars from 0 for the first element and goes up to "length, of list - I".	mg_line = (mg_ mg_ no. mg_ no. mg] print(mg_lint(mg)) stopped: mg_lint(mg_lint) stopped: mg_lint	
indexing	indicating an a time analysis on an access many resource, that you man, marketing states control and are care control and greatly as a realizable as a realiza	<pre># Output: 10 (accessing the first element) print(my_list(-1)) # Output: 10 (accessing the last element using negative indexing)</pre>	
		Syntax:	
		list_name.insert(index, element)	
insert()	The "inserty" method is used to insert an element.	Example:	
		<pre>my_list = [1, 2, 3, 4, 5] my_list_lower(2, 6) print(my_list)</pre>	
		Example:	
Modifying a list	You can use indexing to modify or assign new values to specific elements in the list.	my_liar r(m, my, m, ad, ad) my_liar() = n embrying the second element print(my_liar) # chapt. [a, my, ad, my, ad) # chapt. [b, my, my, ad)	
		print(my_list) # Output: [10, 25, 30, 40, 50]	
		Example 1:	
		mg_lists [18, 28, 28, 46, 40] removed_listers = mg_lists_rep(2) # Removes and returns the element at index 2 removed_listers = mg_lists_rep(2) # Removes and returns the element at index 2 removes_listers = mg_lists_rep(2) # Removes_listers = mg_lists_rep(2) # Removes_listers = mg_lists_rep(2) # Removes_lists_removes_lis	
		# Cutput: 30 grint(sy, list) # Cutput: [10, 20, 48, 58]	
pop()	pop()" method is another way to remove an element from a list in Python. It removes and returns the element at the specified index. If you dusty provide an index to the "pop()" method, it will remove and returns the last element of the list by default	Example 2:	
		my_list = [12, 20, 30, 40, 50] my_list = [12, 20, 10, 40, 50] print(proceed_class(), prop() # Removas and returns the last sleesent print(proceed_class()) # October 30 print(p_list) # October 30, 40, 20, 40]	
		print(removed_alament) # Output: 50 print(my_list)	
	To remove an element from a list. The 'removery' method removes the first occurrance of the specified value.	Example: my_list = [18, 20, 30, 40, 50]	
remove()	To remove an element from a list. The 'removey' method removes the first occurrence of the specified value.	70 14 m = (10, 20, 20, 20, 20, 20) 20 20 20 20 20 20 20 20	
		Example 1:	
reverse()	The 'revenety' method is used to revene the order of elements in a list	my_list = {1, 2, 3, 4, 5} my_list.reverse() print(my_list) 0 Output [3, 4, 2, 2, 3]	
		Syntax: list_name(start:end:step)	
		Example	
Slicing	You can use skining to access a range of elements from a lat.	my_line r[x, y, z, x]. print(n_line) (a) print(n_line) (a) print(n_line) (b) print(n_	
		# Output: [2, 3, 4] (elements from index 1 to 3) print(my_list[3]) # Output: [1, 2, 3] (elements from the beginning up to index 2)	
		<pre>print(my_list(2:)) # Output: (3, 4, 5) (elements from index 2 to the end) grain(my_list(:2:))</pre>	
		Example 1: mv list = (5, 2, 8, 3, 9)	
		my line = (5, 2, 8, 2, 9) my line = (5, 2, 8, 2, 9) my line = (5, 2, 8, 2, 9) print(my line) schape: [1, 2, 5, 8, 9)	
sort()	The 'wortj' method is used to not the elements of a list in according order. If you want to sort the list in descending order, you can pass the 'reverse-'True' argument to the 'wortj' method.	Example 2:	
		## 150	
		print(my,list) # Output: [9, 8, 5, 2, 1]	
Tuple			
Package/Method	Deceription	Code Example Syntac:	
		tuple.count (walue)	
count()	The count) method for a tuple is used to count how many times a specified element appears in the tuple.	Example:	
		fruits ('iaple', 'banam', 'apple', 'corage') pris(fruits.comt('apple')) KCounts the number of times apple is found in tuple. MODIFIC: 2	
		Syntax:	
		tuple.index(value)	
index()	The indext) method in a taple is used to find the first occurrence of a specified value and returns in position (index). If the value is not found, it raises a ValueErmon.	Example:	
		fruits < ('apple', 'banna', 'orange') print(fruits[1]) seturns the value at which apple is present. 6004pt; blanna	
sum()	The sum) function in Python can be used to calculate the sum of all elements in a upide, provided that the elements are numeric (integers or floats).	Syntax:	
"		sun(tople)	

		Example:
min() and max()	Find the smallest (min(t)) or largest (max(t)) element in a tuple.	Example: notice(-) (26, 25, 5, 30) notice(-) (26, 25, 5, 30) notice(-) 5 print(part onder(-)) notice(-) 5 print(part onder(-)) notice(-) 5
len()	Get the number of elements in the topic using lea().	Syste: let(tople) Example: fruits = ('apple', 'hanner', 'orange') point(self-orange) meturus inege of the tuple. disper: 3
