Cheat Sheet: Building Supervised Learning Models

Common supervised learning models

Process Name	Brief Description	Code Syntax
One vs One classifier (using logistic regression)	Process: This method trains one classifier for each pair of classes. Key by preparameters: - infinite from the classifier (e.g., logistic regression) Proc. Can work well for small datasets. Cons: Computationally expensive for large datasets. Common applications: Multiclass classification problems where the number of classes is relatively small.	from sklavnm.multiclass import GoeVodnoClassifier from sklavnm.lineir model import LogisticRegression model = OneVodnoClassifier(LogisticRegression())
One vs All classifier (using logistic regression)	Process: Trains one classifier per class, where each classifier distinguishes between one class and the rest. Key hyperparameters: - entimator: Blass classifier (e.g., Logistic Regression) - initiat (last): Strategy to handle maintchass classification ('ov') - initiation: Strategy to the maintchass classification ('ov') Const. Less accurate for highly imbalanced classes. Common applications: Common in multiclass classification problems such as image classification.	from sklearm.multiclass import Ome/shestClassifier from sklearm.linear_model import LogisticRegression model = OmeroRestClassifier(LogisticRegression()) or from sklearm.linear_model import LogisticRegression model_ova = LogisticRegression(multi_class='over')
Decision tree classifier	Process: A troc-based classifie that splits data into smaller subsets based on feature values. Key by perparameters: - max, depth: Maximum depth of the tree Prox: Easy to interpret and visualize. Prox: Easy to interpret and visualize. Coass: Prone to overfitting if not pruned properly. Common applications: Classification tasks, such as credit risk assessment.	from sklearm.tree import DecisionfreeClassifier model = DecisionfreeClassifier(mag_depth=5)
Decision tree regressor	Processes Similar to the decision tree classifier, but used for regression tasks to predict continuous values. Kee by perparameters: - inus, depth: Maximum depth of the free Prove: Easy to interpret, handles nonlinear dats. Coss: Can overfit and perform poorly on noisy data. Common applications: Regression tasks, such as predicting housing prices.	from sklearn.tree import DecisionTreeRegressor model = DecisionTreeRegressor(mar_depth=S)
Linear SVM classifier	Process: A linear classifier that finds the optimal hyperplane separating classes with a maximum margin. Key by perparameters. Key by perparameters. * kernel : Type of kernel fluction of linear': poly': rbf', rctc.) * kernel : Type of kernel fluction of linear': poly': rbf', rctc.) * gamma': Kernel coefficient (only for 'if', poly': ctc.) * Pross: Effictive for high-dimensional spaces. Common applications: Text classification and image recognition.	from sklearn.svm import SVC model = SVC(kernel='linear', C=1.6)
K-nearest neighbors classifier	Process: Classifies data based on the majority class of its nearest neighbors. Key by perparameters: Key by perparameters: "weights: Weight financion used in prediction ("uniform" or "distance") - "weights: Weight financion used in prediction ("uniform" or "distance") - "algorithm". Signorithm used no recomplet the nearest neighbors ("auto", "ball_tree", "kd_tree", "brute") Proxs: Simple and effective for small datasets. Const. Computationally expensives and the dataset grows. Common applications: Recommendation systems, image recognition.	from sklearn.neighbors import DkeighborsClassifier model = TheighborsClassifier(n_neighbors-5, weights='uniform')
Random Forest regressor	Process: An ensemble method using multiple decision trees to improve accuracy and reduce overfitting. Key byperparameters: - 'n_estimators': Number of trees in the forest - 'n_estimators': Number of trees in the forest - 'max_depth'. Namenum depth of each tree. Proc. Less prome to overfitting than individual decision trees. Common applications: Regression tasks such as predicting sales or stock prices.	from sklearm.ensemble import RandomforestRegressor model = RandomforestRegressor(n_extimators=180, max_depth=5)
XGBoost regressor	Process: A gradient boosting method that builds trees sequentially to correct errors from previous trees. Key byerparameters: - in estimators: Number of boosting rounds - l'earning, rate: Step size to improve occuracy - l'anax, depth: Maximum depth of each tree Pross: High accure, and works well with large datasets. Cons: Computationally intensive, complex to tune. Common applications: Predictive modeling, especially in Kaggle competitions.	import aghost as agb model = agh.XGBRegressor(n_estimators=180, learning_rate=0.1, max_depth=5)

Associated functions used

Method Name	Brief Description	Code Syntax
OneHotEncoder	Transforms categorical features into a one-hot encoded matrix.	from sklearm.preprocessing import OneNortEncoder encoder = OneNortEncoder(parsex=Ealss) encoded_data = encoder.fit_tramsform(categorical_data)
accuracy_score	Computes the accuracy of a classifier by comparing predicted and true labels.	from sklearm.metrics import accuracy_score accuracy = accuracy_score(y_true, y_jmed)
LabelEncoder	Encodes labels (target variable) into numeric format.	from sklearn.preprocessing import tabelincoder encoder = tabelincoder() encoded_labelis = encoder-fit_transform(labelis)
plot_tree	Plots a decision tree model for visualization.	from sklearn.tree import plot_tree plot_tree(model, max_depth=3, filled-True)
normalize	Scales each feature to have zero mean and unit variance (standardization).	from skiezem_proprocessing import normalize normalize_data = normalize(data = normalize(data, norm=12')
compute_sample_weight	Computes sample weights for imbalanced datasets.	from sklearn.utils.class_weight import compute_sample_weight weights = compute_sample_weight(class_weight-balanced", y-y-)
roc_suc_score	Computes the Area Under the Receiver Operating Characteristic Curve (AUC-ROC) for binary classification models.	from sklearm.metrics import roc_muc_score auc = roc_muc_score(y_trum, y_score)
