Cheat Sheet: Python Data Structures Part-2

Dictionaries

Package/Method	Description	Code Example		
-	·	Example:		
Creating a Dictionary	A dictionary is a built-in data type that represents a collection of key-value pairs. Dictionaries are enclosed in only braces ().	dict_name = () #Creates an empty dictionary preson = ("name": "John", "Age": 30, "city": "New York")		
		parson = { "name": "John", "age": 30, "city": "New York"}		
	You can access the values in a dictionary using their corresponding twys.	Syntax:		
		Value = dict_name(*bay_name*)		
Accessing Values		Example:		
		name = person("name") age = person("age")		
		Syntax:		
		dict_name[key] = value		
Add or modify		Example:		
		person["Country"] = "USA" # A new entry will be created. person["city"] = "Chicago" # Update the existing value for the same key		
		Syntax:		
del	Removes the specified key-value pair from the dictionary. Raises a toyterer if the key does not exist.	del dict_name(kmy) Example:		
		Example: del person("Country")		
		out person (country)		
		Syntax:		
update()		dict_name.update((key: value))		
upune()	The update() method neeges the provided decionary into the existing decionary, adding or updating key-value pairs.	Example:		
		person.update(("Profession": "Doctor"))		
	The clase() method empties the decionary, removing all key-value pairs within it. After this operation, the decionary is still accessable and can be used further.	Syntax:		
		dict_name.clear()		
clear()		Example:		
		grades.clear()		
	You can check for the existence of a key in a decisionary uning the in keyword	Example:		
key existence		if "name" in person:		
		print("Name exists in the dictionary.")		
	Creates a shallow copy of the dictionary. The new dictionary contains the same key-value pairs as the original, but they remain distinct objects in memory.	Syntax:		
		new_dict = dict_mame.copy()		
copy()		Example:		
		new_person = person.copy() new_person = dict(person) # another way to create a copy of dictionary		
	Retrieves all keys from the dictionary and converts them into a list. Useful for iterating or processing keys using list methods.	Syntax:		
keys()		<pre>beys_list = list(dict_name.keys())</pre>		
1.		Example:		
		person_keys = list(person.keys())		
		Syntax:		
1		values_list = list(dict_name.values())		
values()		Example:		
		person_values = list(person.values())		
	Perform the subscript results and consent American Secretarian Secre	Syntax:		
		item_list = list(dict_name.items())		
items()		Example:		
		info = list(person.items())		
L				
Sets				

ets

Package/Method	Description	Code Example
		Syntax:
	Elements can be added to a set using the 'add()' method. Deplicates are automatically removed, as sets only store unique values.	set_name.add(element)
add()		Example:
		fruits.add("mango")
		Syntax:
	The 'clear()' method removes all elements from the set, resulting in an empty set. It updates the set in-place.	set_name:clear()
clear()		Example:
		fruits.clear()
		Syntax:
	The 'copy()' method creates a shallow copy of the set. Any modifications to the copy won't affect the estigned set.	new_set = set_name.copy()
copy()		Example:
		new_fruits = fruits.copy()
		Example:
Defining Sets	A set is an unordered collection of unique elements. Sets are enclosed in curby braces (). They are useful for noting distinct values and performing set operations.	empty_set = set() #Creating am fmpty Set fruits = ("apple", "banana", "orange")
		Syntax:
		set_name.discard(element)
discard()	Use the 'discasely' method to remove a specific element from the set. Ignores if the element is not found.	Example:
		fruits.discard("apple")
		Syntax:
	The 'ionsheet)' method checks if the current set in a subset of another set. It returns True if all elements of the current set are greener in the other set, otherwise False.	is_subset = set1.issubset(set2)
issubset()		Example:
		is_subset = fruits.issubset(colors)
		Syntax:
	The "iscurrenced" method checks if the rument set is a superset of mother set. It returns True if all elements of the other set are resent in the current set otherwise. False	is_superset = set1.issuperset(set2)
issuperset()		Example:
		is_superset = colors.issuperset(fruits)
pop()	The 'pop()' method returness and returns an arbitrary demonst from the set. It raises a "KeyEtime" if the set is empty. Use this method to remove elements when the order doesn't matter.	Syntax:
		removed_element = set_name.pop()
1		Example:

			removed_fruit = fruits.pop()
			Syntax: set_name.rumove(element)
remove()	Use the 'removest') method to remove a specific element from the set. Raises a 'Keyfirnor' if the element is not found.	Example: fruits.rumow("banand")	
Set Operations			System union_set = set_union(set_) difference_set = set_difference(set_) difference_set = set_difference(set_) sys_diff_set = set_union(set_difference(set_)) Example: contained = freits_union(colors) contained = freits_union(colors) union_set_diff_set_set_difference(set_set_) sys_diff_set_set_set_difference(set_set_set_set_set_set_set_set_set_set_
update()		The industry surface has been upon upon probability in the cell transition of distance.	Symm: set_mam_update(iterable) Emmple: froits.update(["sind.", "grope"])
